That means you've got access to an entire library of classic literature that you can read on the computer or on a variety of mobile devices and eBook readers.

### Wing Design Nasa Plane Wing

For almost a hundred years most planes have looked like a tube with wings, but that may change thanks to NASA research. Engineers at NASA's Langley Research Center in Hampton, Va., are testing a design for a flying wing, called a blended wing body or BWB, which would be more fuel efficient and environmentally friendly than today's aircraft.

Popular Science reporter Rob Verger writes that MIT and NASA researchers have developed a new design for a plane wing that can change shape mid-flight. As the plane wing is assembled from hundreds of different parts, it could be programmed in a specific way to control the "response that it has to an aerodynamic load," explains graduate student Benjamin Jenett.

The new wing design, which is about the size of a one-seater plane wing, was tested in a NASA wind tunnel. Its results were better than anticipated and have been published in Smart Materials and Structures. "The fact that most aircraft are the same shape is because of expense. It's not always the most efficient shape," said Jenett.

The air resists the motion in the form of aerodynamic drag. Modern airliners use winglets on the tips of the wings to reduce drag. The turbine engines , which are located beneath the wings, provide the thrust to overcome drag and push the airplane forward through the air.

An oblique wing is a variable geometry wing concept. On an aircraft so equipped, the wing is designed to rotate on center pivot, so that one tip is swept forward while the opposite tip is swept aft. By changing its sweep angle in this way, drag can be reduced at high speed without sacrificing low speed performance. This is a variation on the classic swing-wing design, intended to simplify construction and retain the center of gravity as the sweep angle is changed.

How Wings Lift the Plane. Airplane wings are shaped to make air move faster over the top of the wing. When air moves faster, the pressure of the air decreases. So the pressure on the top of the wing is less than the pressure on the bottom of the wing. The difference in pressure creates a force on the wing that lifts the wing up into the air.
